

User-created Functions

Chapter 03a

Lesson Objectives

- Review Functions already used
- What are user-created functions?
- User-created Function Syntax
- return Statement
- Global and Local Variable Scope

What is a user-created function?

- A reusable section of code with a name that simplify something.
- Give the function a descriptive self explanatory name.

Why create functions?

- Code reuse
 - You are doing the same thing over and over again.
- Simplify your code
 - Functions have names to define what they do.
 - Breaks down complex blocks of code.
- Easier to make changes
 - If its only been written once, you only have to update it once.

You have already used functions!

- `print()`
- `input()`
- `len()`
- `str()`
- `int()`
- `float()`

User-created Functions

- A function is a **mini program** within your main program.
- User can use the function by calling it and **using it over and over** and in different places in the entire program.
- Code inside the Function will not be executed, unless the **function is called**.

FUNCTION SYNTAX:

def **function_name**():

indented block of code

code

code

return

#**descriptive** function name

#end line with **colon**

#**exit** the function

```
def hello():
```

```
    print('Howdy!')
```

```
    print('Howdy!!!')
```

```
    print('Hello there.')
```

#define function

hello()

#calls the function

hello()

#calls the function

hello()

#calls the function

How do you call a function? – simply use its name

```
def printMessage():
```

```
    print('Biba GCC')
```

```
    return
```

#define function

#exits the function

printMessage()

#calls the function

return Statements Syntax

Syntax:

return variable value or expression

Examples:

return <nothing after>

return 'it is certain'

return message

return bill

return Statements Syntax

- If a function does not have a return statement, Python adds **return None** to the end of the function.
- If a function has a return statement with no variable value or expression, the function also **returns the value None**
- **None** – absence of a value.

If Function **needs data, pass parameters** into the function

SYNTAX:

```
def function_name(parameters):    #use descriptive names
```

Example:

```
def printMessage(message)
    print(message)
    return
```

```
printMessage('Biba GCC!')
```

Two red arrows originate from the 'printMessage' call in the example code. One arrow points from the function name 'printMessage' to the 'def printMessage' line in the function definition. The other arrow points from the string parameter 'Biba GCC!' to the 'message' parameter in the function definition's parentheses.

#define function

#message parameter passed into

#function

#exits the function

#function is called

#passes parameter to the function.

Function returns data using the keyword return

```
def tax(bill):  
    bill = bill * 1.08  
    print('Your bill is ', bill)  
    return bill  
  
meal_cost = 100  
  
#calls the tax Function, passes the parameters to the function  
meal_with_tax = tax(meal_cost)  
  
#goes here after execution of return statement
```

(#or bill = bill * (bill *.08)

The diagram consists of two red arrows. One arrow starts from the **tax** parameter in the function call `tax(meal_cost)` and points to the **bill** parameter in the function definition `def tax(bill):`. The second arrow starts from the **return bill** statement in the function definition and points to the **meal_with_tax** variable in the function call, illustrating the return value being passed back to the caller.

Global and Local Scope: **Local**

- Variables assigned in a called function, exists in that function's **local scope** and are called a local variable. When the function returns, the local scope is destroyed, and the local variables are forgotten.
- Code in the **global scope** cannot use any local variable.
- Code in one function's local scope cannot use variables in any other local scope.
- You can use same name for different variables if they are in different scopes.

Global and Local Scope: **Global**

- Variables assigned outside all functions, exists in the **global scope** and are called a global variable.
- Local scope can access global variables.
- Code in the global scope cannot use any local variable.

#Parameters, a lower and upper bound number

#Returns the sum of the numbers from lower through upper

```
def summation(lower, upper):
```

```
    result = 0
```

```
    while lower <= upper:
```

```
        result = result + lower
```

```
#variable for summing
```

```
        lower = lower + 1
```

```
#counter
```

```
lower = int(input('Enter a lower bound number'))
```

```
upper = int(input('Enter a upper bound number'))
```

```
answer = summation(lower, upper)
```

```
#calls the function
```

```
print(answer)
```

```
#What is the error?
```

#Parameters, a lower and upper bound number

#Returns the sum of the numbers from lower through upper

```
def summation(lower, upper):
```

```
    result = 0
```

```
    while lower <= upper:
```

```
        result = result + lower
```

```
#variable for summing
```

```
        lower = lower + 1
```

```
#counter
```

```
    return result
```

```
lower = int(input('Enter a lower bound number'))
```

```
upper = int(input('Enter a upper bound number'))
```

```
answer = summation(lower, upper)
```

```
#calls the function
```

```
print(result)
```

```
#What is the error?
```

#Parameters, a lower and upper bound number

#Returns the sum of the numbers from lower through upper

```
def summation(lower, upper):
```

```
    result = 0
```

```
    while lower <= upper:
```

```
        result = result + lower
```

```
        #variable for summing
```

```
        lower = lower + 1
```

```
        #counter
```

```
    return result
```

```
lower = int(input('Enter a lower bound number'))
```

```
upper = int(input('Enter a upper bound number'))
```

```
answer = summation(lower, upper)
```

```
#calls the function
```

```
print(answer)
```
